

# Word measures on unitary groups

Michael Magee (Durham)

November 9, 2017

**Abstract:** This is joint work with Doron Puder (Tel Aviv University).

For a positive integer  $r$ , fix a word  $w$  in the free group on  $r$  generators. Let  $G$  be any group. The word  $w$  gives ‘word map’ from  $G^r$  to  $G$ : we replace the generators in  $w$  by the corresponding elements of  $G$ . We again call this map  $w$ . The push-forward of Haar measure under  $w$  is called the  $w$ -measure on  $G$ . We are interested in the case  $G = U(n)$ , the compact Lie group of  $n$ -dimensional unitary matrices. A motivating question is: to what extent do the  $w$ -measures on  $U(n)$  determine algebraic properties of the word  $w$ ?

We proved in our first paper that one can detect the ‘stable commutator length’ of  $w$  from the  $w$ -measures on  $U(n)$ . Our main tool was a formula for the Fourier coefficients of  $w$ -measures; the coefficients are rational functions of the dimension  $n$ , for reasons coming from representation theory.

We can now explain all the Laurent coefficients of these rational functions in purely topological terms. I’ll explain all this in my talk, which should be broadly accessible and of general interest. I’ll also invite the audience to consider some remaining open questions.
